6 H T	(a)			Indicative content: The term latent is used because the energy supplied does not raise the temperature of the substance but merely goes to enable the change of state to take place [per kg]. The term “fusion” refers to the change from a solid to liquid at its melting point and the energy supplied goes into breaking bonds between molecules. In the case of fusion, only a small number of bonds are broken. The latent heat of vaporisation refers to a liquid changing to a gas and is always a much larger value because the change requires a much larger number of bonds to be broken.	6				0	0
