

5. The diagram shows a tower crane used on a new building in the centre of Cardiff. A weight is lifted on the long arm and a counterweight on the short arm keeps the crane from toppling over.

- (a) A group of students investigate a model of the crane by hanging weights from a horizontal metre ruler.

They hang a 2.0 N weight at one end, 50 cm from the pivot and another weight of 2.5 N somewhere on the other side of the pivot to make it balance.

- (i) Use the equation:

$$\text{moment} = \text{force} \times \text{distance}$$

to calculate the anticlockwise moment (in N cm) of the 2 N weight about the pivot. [2]

Moment = N cm

- (ii) Use your answer to part (i) and the equation:

$$\text{distance} = \frac{\text{moment}}{\text{force}}$$

to calculate the distance that the 2.5 N weight should be placed from the pivot for the ruler to balance. [2]

Distance = cm

- (iii) Explain why it would be impossible to balance the 2 N weight on the end of the ruler if the 2.5 N weight is replaced with a 1.5 N weight. [2]

.....

.....

.....

- (b) A particular tower crane is capable of lifting a maximum mass of 15 000 kg. Use the equation:

$$\text{weight} = \text{mass (kg)} \times \text{gravitational field strength}$$

to calculate the weight of this mass. [2]
[gravitational field strength, $g = 10 \text{ N/kg}$]

Weight = N
