

8. Most plants are unable to survive in waterlogged soil because air spaces between soil particles become filled with water.

The photomicrograph shows a transverse section through the root of a dicotyledonous plant.

Describe the pathways by which water passes from the cells of the epidermis across the cortex of the root and then into the vascular tissue of a plant growing in well-drained soil.
Explain why a plant growing in waterlogged soil experiences a reduction in root pressure.
