6	A: Hormonal control of ovulation - FSH stimulates the development of follicles in the ovary. - follicle cells produce oestrogen - which inhibits the production of FSH - and stimulate the production of LH. - LH stimulates production of more oestrogen - and oestrogen stimulates production of LH. - Eventually the LH levels cause ovulation. - increase in FSH levels also aids ovulation. - The corpus luteum produces progesterone. - Which is needed for development of endometrium. B: Similarities - Hormonal control similar for both/ same hormones involved in both - Copulation affects ovulation - Copulation increases production of LH and FSH - Copulation increases progesterone levels C: Differences - Rabbits only ovulate after copulation/ In humans ovulation occurs even if no copulation - Ovulation is not cyclical in rabbits/ ovulation is cyclical in humans - If no copulation LH and FSH remain low in rabbits - FSH level reach zero in rabbits/ do not reach zero in humans - FSH has single peaks in rabbits/ twin peaks in humans	3	2	4
