

9. (a) Addition of a solution containing  $\text{Ag}^+(\text{aq})$  to solutions containing halide ions such as chloride, bromide or iodide causes precipitates to form.

- (i) Give the colours of the precipitates formed with chloride, bromide and iodide ions. [1]

chloride ions .....

bromide ions .....

iodide ions .....

- (ii) The standard enthalpy change of formation of  $\text{AgCl}(\text{s})$  is  $-127.1 \text{ kJ mol}^{-1}$ .

Use the data below to calculate the standard enthalpy change of formation of  $\text{AgBr}(\text{s})$  and hence show which of the two silver halides is more stable with respect to its elements. You **must** show your working. [4]

| Reaction                                                                                | Standard enthalpy change, $\Delta H^\theta / \text{kJ mol}^{-1}$ |
|-----------------------------------------------------------------------------------------|------------------------------------------------------------------|
| $\text{Ag}(\text{s}) \longrightarrow \text{Ag}^+(\text{aq}) + \text{e}^-$               | +105.6                                                           |
| $\text{Br}_2(\text{l}) + 2\text{e}^- \longrightarrow 2\text{Br}^-(\text{aq})$           | -243.1                                                           |
| $\text{AgBr}(\text{s}) \longrightarrow \text{Ag}^+(\text{aq}) + \text{Br}^-(\text{aq})$ | +84.4                                                            |

 .....  
 .....

- (b) The standard electrode potential for the half-equation below is +0.80 V.

- (i) When a piece of copper metal is placed in a solution of silver nitrate, a displacement reaction occurs.

I. Write the **ionic** equation for this displacement reaction. [1]

.....

II. State what information this provides regarding the standard electrode potential for the  $\text{Cu}(\text{s})|\text{Cu}^{2+}(\text{aq})$  half-cell. Give a reason for your answer. [2]

.....

.....

.....

- (ii) The apparatus below was assembled with the  $\text{Pb}(\text{s})|\text{Pb}^{2+}(\text{aq})$  half-cell under standard conditions connected to the  $\text{Ag}(\text{s})|\text{Ag}^+(\text{aq})$  half-cell. The silver is the positive electrode.

The value on the high-resistance voltmeter was recorded with different concentrations of silver ions used in the  $\text{Ag(s)}|\text{Ag}^+(\text{aq})$  half-cell. The results are shown below.

| Concentration of $\text{Ag}^+(\text{aq})$<br>/ $\text{mol dm}^{-3}$ | Value recorded on high-resistance voltmeter<br>/ V |
|---------------------------------------------------------------------|----------------------------------------------------|
| 1.0                                                                 | 0.93                                               |
| 0.1                                                                 | 0.87                                               |
| 0.01                                                                | 0.81                                               |
| 0.001                                                               | 0.75                                               |
| 0.0001                                                              | 0.69                                               |

- I. Calculate the value of the standard electrode potential for the  $\text{Pb(s)}|\text{Pb}^{2+}(\text{aq})$  half-cell.

[2]

$$E^\theta = \dots\dots\dots \text{V}$$

- II. Explain why the value recorded on the voltmeter becomes less positive as the concentration of silver ions decreases.
