

5. The rate of reaction between hydrochloric acid and calcium carbonate was studied. Two experiments, **A** and **B**, were carried out. The same concentration of acid and the same mass of calcium carbonate were used, with the acid in excess each time. The volume of gas produced was measured for 60 seconds. The results of these experiments are shown in the graphs.

- (a) Using the particle theory, state and explain **two** factors that may be responsible for the higher rate seen in experiment **A**. [4]

.....

- (b) State how the graphs show that the same mass of calcium carbonate was used in both experiments. [1]
