					AO1	AO2	AO3	Total	Maths	Prac
10.	(a)	(i)		Indicative content $\text{RX} + \text{OH}^- \rightarrow \text{ROH} + \text{X}^-$ (any halogenopropane / NaOH) mechanism is nucleophilic substitution C—halogen bond must be broken for the reaction to take place based on electronegativity, carbon atom in the chlorocompound is the most δ^+ suggests that chlorocompound would react fastest based on bond enthalpies, the C—I bond is the weakest suggests that iodo compound would react fastest iodo compound does in fact react fastest so effect of bond strength effect is more significant than effect of polarity	1	1
