

6. (a) State what is meant by the work function,  $\phi$ , of a metal surface. [1]

.....

.....

- (b) Sodium will undergo the photoelectric effect when illuminated by visible light, but zinc requires ultraviolet radiation. **Explain** which material has the greater work function. [1]

.....

.....

- (c) (i) Use Einstein's photoelectric effect equation to show that the maximum wavelength,  $\lambda_{\text{max}}$ , for emission is given by the equation: [2]

$$\lambda_{\text{max}} = \frac{hc}{\phi}$$

.....

.....

.....

- (ii) A mixture of red ( $\lambda = 650 \text{ nm}$ ), green ( $\lambda = 550 \text{ nm}$ ) and blue ( $\lambda = 450 \text{ nm}$ ) light is incident on a metal surface of work function of  $3.7 \times 10^{-19} \text{ J}$ . Determine which wavelength or wavelengths of light will be **unable** to release electrons from the metal surface. [2]

.....

.....

.....

.....

- (iii) Explain, in terms of photons, whether or not the intensity of the light will affect the maximum kinetic energy of the released electrons. [2]

.....

.....

.....
