

12. (a) A series of experiments is performed on three white solids, **A**, **B** and **C**. All contain the same Group 2 metal ion. Compound **A** is the metal hydroxide.

The experiment is summarised below.

- The compounds give a definite colour in a flame test
- Compound **A** is only slightly soluble in water
- Compound **B** is insoluble in water

- (i) A student correctly identified the metal ion as calcium. Give **two** reasons why she came to that conclusion. [2]

.....

.....

.....

.....

- (ii) Name compound **B**. [1]

.....

- (iii) 0.110 g of compound **C** was completely neutralised by 26.10 cm³ of 0.150 mol dm⁻³ hydrochloric acid.

Given that 1 mol of compound **C** reacts with 2 mol of acid, calculate the relative formula mass of compound **C** and hence confirm that the metal ion is calcium.

You **must** show your working.

[2]

- (b) Group 2 metals are not the only elements that form 2+ ions.

A sample of an element has two isotopes, one with 70 neutrons and the other 72 neutrons. This element forms a 2+ ion containing 48 electrons. The relative abundances of the isotopes are 57.9% and 42.1% respectively.

Calculate the relative atomic mass of the element. Give your answer to **four** significant figures. [3]

$A_r =$

- (c) Describe, giving **brief** experimental details, how you would obtain the maximum amount of magnesium carbonate from a known mass of magnesium, in a **two-stage** process. Include appropriate chemical / ionic equations in your answer. [6 QER]
