

9. (a) 1.598 g of an acid chloride, RCOCl , was added to water. The aqueous solution contained hydrochloric acid and a carboxylic acid, $\text{R} - \text{COOH}$, where R is an alkyl group

- (i) State the type of reaction occurring. [1]

- (ii) This acidic solution was titrated with $0.400 \text{ mol dm}^{-3}$ aqueous sodium hydroxide, using a suitable indicator. Both acids were just neutralised by 75.00 cm^3 of the sodium hydroxide solution.

Use the results to calculate the relative molecular mass of the acid chloride. [3]

M_r

- (iii) The low resolution ^1H NMR spectrum of the acid chloride showed two signals in the peak area ratio of 6:1.

Use this information and the relative molecular mass of the RCOCl , obtained in part (ii), to find the structure of the acid chloride. [2]

- (b) (i) The acid chloride, benzene-1,4-dicarbonyl dichloride, $\text{ClOC} - \text{C}_6\text{H}_4 - \text{COCl}$ is made by reacting benzene-1,4-dicarboxylic acid with phosphorus(V) chloride. The other products of this reaction are hydrogen chloride and phosphoryl trichloride, POCl_3 .

Give the equation for this reaction.

[1]

- (ii) Benzene-1,4-dicarbonyl dichloride reacts with benzene-1,4-diamine to give a polyamide.

Show the repeating unit for this polyamide.

[1]

- (c) Nylon polyamides that are produced from starting materials with a different number of carbon atoms are given numbers. For example Nylon 4,5 has a 4-carbon diamine fragment and a 5-carbon dicarboxylic acid fragment.

Butane-1,4-diamine can be used as a starting material for this polyamide. This can be produced in a two-stage reaction from butane-1,4-diol.

- (i) State the name of reagent(s) **A**.

[1]

.....

- (ii) State the name of reagent(s) **B**.

[1]

.....

(iii) State the type of mechanism occurring in Stage 2.

[1]

(iv) Draw the **skeletal** formula of the 5-carbon containing dicarboxylic acid used to produce Nylon 4,5.

[1]

(d) The depolymerisation of polyamides and polyesters present a number of difficult problems as these polymers are very stable and only slowly decompose in the environment.

Poly(ethyleneterephthalate) (PET) is very difficult to hydrolyse but a new process using specific enzymes is proving promising. In this process 90% of PET is depolymerised into benzene-1,4-dicarboxylic acid.

Calculate the mass of benzene-1,4-dicarboxylic acid produced from 75 kg of PET if the yield from this hydrolysis is 90%.

[3]

mass of benzene-1,4-dicarboxylic acid produced = kg
